### FOREWORD

This Appendix, prepared as a supplement to final report NADC-77183-30 dated December 1976, presents results of static and fatigue tests of a graphite/epoxy wing box structure designed and fabricated by the Columbus Aircraft Division (CAD) of Rockwell International Corporation under contract N62269-74-C-0577. These tests were conducted by the Navy at the Naval Air Development Center, Warminster, PA. during the period August-September 1978. Static loads to 150% of design limit load for the critical carrier based landing condition were applied to the composite wing box structure followed by a two lifetime fatigue spectrum loading with no evidence of structural damage or deformation. Descriptions of the test setup, applied loadings, strain gage data, deflection transducer data, and comparisons of predicted vs recorded strain and deflection measurements are presented.

## C-1 INTRODUCTION

This Appendix presents results of static and fatigue tests of a graphite/epoxy wing box structure designed and fabricated by the Columbus Aircraft Division (CAD) of Rockwell International Corporation under contract N62269-74-C-0577. These tests were conducted by the Navy in the structural test facility located at the Naval Air Development Center, Warminster, PA. Static loadings to 150% of design limit load were completed on 9 August 1978 with no evidence of structural damage or permanent deformation. These static load tests were followed by a two-lifetime fatigue spectrum loading which was completed on 20 September 1978 with no evidence of damage or deformation of the composite wing box structure.

Setup and performance of test operations were accomplished under the direction of J. J. Minecci, test director, and Ralph Vining, test engineer of NADC. The NADC project engineer for the XFV-12A composite wing box evaluation was M. S. Rosenfeld. All or portions of this series of tests were witnessed by the above listed personnel and by Dr. S. L. Huang of NADC and D. N. Ulry of the Columbus Aircraft Division (CAD).

### C-2 DESCRIPTION OF TEST ARTICLE

The composite wing structure consists of a graphite/epoxy wing box section approximately 88 inches long, 80 inches wide and 12 inches thick. The test specimen, illustrated in Figures C-1 through C-5, is representative of a section of the XFV-12A main wing box structure extending from the centerline of airplane outboard beyond the mid-span of the wing. The test box structure is representative of all aspects of an actual wing structure including provisions for internal fuel and wing to fuselage attachment fittings.

Construction of the composite wing box structure is described in detail in the NADC-77183-30 final report and contains the following salient features:

- (1) Honeycomb sandwich cover skins consisting of graphite/epoxy face sheets and glass/phenolic honeycomb core.
- (2) Honeycomb sandwich front and intermediate spars.
- (3) Solid graphite/epoxy laminate B.P. 33 rib.
- (4) Aluminum rear spar, centerline rib and wing/fuselage attachment fittings.
- (5) Adhesively bonded lower cover skin to spar attachment and mechanically fastened upper cover to sub structure attachment.

## C-2 DESCRIPTION OF TEST ARTICLE (Cont'd.)

Structural test provisions built into the wing box test section include bolting attachments integral with the aluminum center line rib as shown in Figure C-4 and steel tip loading plates as shown in Figure C-5.

The actual XFV-12A wing is bolted to the fuselage with a three point attachment as shown in Figure C-6 with one front spar attachment at the centerline of the airplane, one L.H. and one R.H. rear spar attachment at B.P. 33.93. For the purpose of this test a L.H. portion of the wing box was rigidly supported along the centerline rib and loads, as determined from a NASTRAN analysis representing the test box specimen and structural test restraints, were applied at the outboard end of the specimen. Statically determinate wing/fuselage attachment loads were applied at the B.P. 33.93 aft wing/fuselage attachment fitting. Figures C-7 and C-8 present a summary of the differences in stress distributions in the upper and lower cover skins as determined from the NASTRAN analysis of the actual wing attachment provisions versus the test article restraint conditions. The small percentage of difference determined in this analysis verifies the rationale and economy of constructing only a L.H. portion of the wing box for full scale structural testing.

#### C-3 CRITICAL TEST LOAD CONDITION

The critical design loading for the XFV-12A wing structure is a maximum vertical carrier based landing condition. The maximum operational loads for this condition are considered "ultimate" for design and test purposes and are equivalent to 150% of design limit load. Test loads to be applied to the composite wing box test section are shown in Figure C-9. Distribution of the test loads at the outboard end of the test specimen at rear spar Station 79.54 is shown in Figure C-10.

### C-4 TEST SETUP

## C-4-1 Support and Loading Arrangement

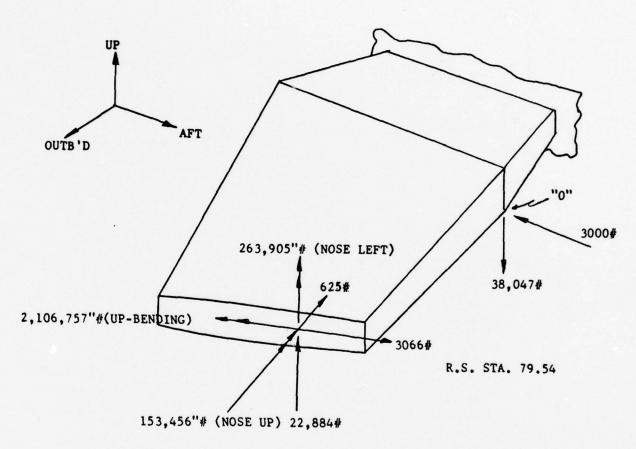

The composite wing box test specimen was mounted approximately ten feet above the floor of the structural test laboratory with the wing reference plane parallel to the plane of the floor as shown in Figure C-11 and C-12. In this setup the centerline root rib was securely bolted to a series of vertical I-beams to provide the basic cantilever support for the test specimen. Twelve hydraulic actuator jacks were used to apply the test loads specified in paragraph C-3. Six actuators mounted parallel to the wing reference plane (three above the specimen and three below the specimen as shown in Figure C-13) applied moment load to the tip loading fixture. Load from these actuators was reacted at the root support beams.

Four actuators (number 7, 8, 9, 10) applied vertical shear load & torque to the tip loading fixture and one actuator (number 11) applied drag load to the tip loading fixture as shown in Figure C-14. One actuator (number 12) was used to apply the specified vertical and drag load at the B.P. 33.93 wing/fuselage attachment fitting. Figure C-15 presents dimensions of the tip moment loading beams. Figures C-16 and C-17 show forward and aft views of the overall test setup. All actuators and loading fixtures were counterbalanced for 1G dead weight.

## C-4-2 Strain Gage Locations

Axial and rosette strain gages were located at selected locations on the wing box cover skins and spars as shown in Figure C-18. Graphite/epoxy cover skin strains were measured with rosette gages at twelve locations (gages 1 through 12) on the upper and lower mold line surfaces of the wing box as specified in Figure C-18. Rosette gages were also located on the inner cover skin surfaces at gage locations 1 and 5. The "A" leg of these rosette gages was mounted parallel to the rear spar plane with the exception of gage 12 which was mounted parallel to the front spar plane.

## C-4-2 Strain Gage Locations (Cont'd.)

Gages (13) through (17) are rosette gages located on the webs of the front spar, aft intermediate spar and aluminum rear spar.

Gage locations 18, 19, and 20 are axial gages mounted on the upper and lower caps of the aluminum rear spar and aluminum rear spar splice joint.

Gage locations 21, and 22) are axial gages mounted on the upper and lower caps of the aluminum centerline rib splice plate.

## C-4-3 Deflection Transducer Locations

Vertical deflections of the lower surface of the wing box relative to a ground plane were measured at nineteen locations (transducer (1) through (9)) as shown on Figure C-19. Measurements were obtained with deflection transducers attached by wires to small blocks bonded to the lower cover which are visible in the photo of Figure C-12.

Rotation at the tip of the wing box structure along the chord of R.S. Sta. 79.54 was measured with twelve deflection transducers (transducer 20 through 32) mounted to the tip loading fixture as shown in Figure C-20.

Rotation of the root support was measured with deflection transducers (transducers 32 through 35 ) located at the front and rear spar junction with the centerline rib. Root rotation was determined by measurement of the inboard-outboard movement at the end of tubes bonded to the upper and lower surfaces of the root rib. Deflections were measured at points fifteen inches above and below the wing reference plane.

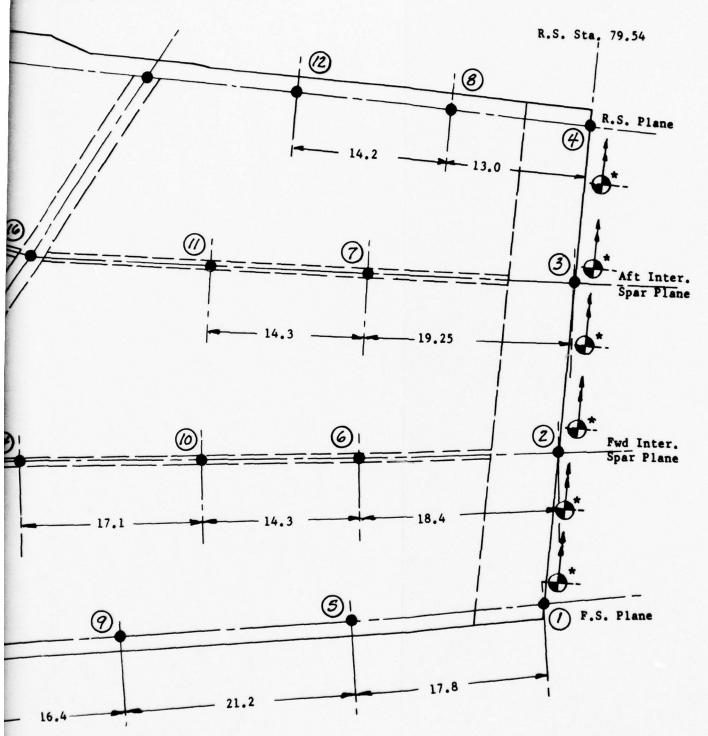

### C-4-4 Load Application and Data Collection

All loads were applied with computer programmed commands to the hydraulic loading jacks and monitored with continuous feed back from the corresponding load cells. Each of the twelve loading jacks were balanced to within one percent of the prescribed load level at each increment of load prior to recording strain and deflection measurements. Approximately 145 channels of strain and deflection data were recorded on magnetic tape and printed on paper tape while holding load at each loading increment. Transducers indicating locations of peak strain and deflection were manually monitored at each loading increment for any evidence of non-linear behavior.

### NOTES:

All deflection transducers are located on front spar, rear spar, or inter. spar lines and are located at NASTRAN node points.

Figure C-20 Tip Rotation Transducer Locations

### C.5 STATIC TEST RESULTS

#### C.5.1 Strain and Deflection Measurements

Static test loadings to 100% of design limit load were completed on 8 August 1978 and static test loadings to 150% of design limit load were completed on 9 August 1978.

Strain and deflection measurements for the 100% load test are presented in Table C.1. Loading increments for this test were 0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 80, 60, 40, 20, 0 percent of limit load. Channel numbers are assigned to each strain gage leg as indicated in the table. Strain gage numbering code is as follows:

- 1 AU denotes strain gage location 1 (Ref. Fig. C-18)
  "A" leg of strain gage (Ref. Fig. C-18), Outer
  surface of upper skin
- 5 BL denotes strain gage location 5 "B" leg of strain gage, Inner surface of lower skin

Strain and deflection measurements for the 150% load test are presented in Table C-2. Loading increments for this test were 0, 20, 40, 60, 80, 100, 110, 120, 130, 140, 150, 140, 120, 100, 80, 60, 40, 20, 0 percent of limit load.

Exceptional linearity and repeatability of strains and deflections are evident in both the 100% and 150% load test data. Plots of the maximum reading cover strain gages (Gage 1 AU and Gage 2 AU) and the peak deflection gage (Transducer 1) are presented in Figures C-21 and C-22 respectively. These plots show consistent linearity throughout the entire range of loadings from 0 to 150%. These plots also show the repeatability of the strain and deflection behavior between the 100% and 150% load test applications. The 150% D.L.L. strains for Rosette Gage 1U resulted in the highest recorded laminate normal principal stress. This peak stress value was -32,644 psi which compared favorably with the 35,000 psi maximum design goal mutually agreed upon by Rockwell and the Navy program monitor as a conservative stress limit to account for environmental degradation and material property scatter effects which might be encountered in a production aircraft fleet.

Table C-3 presents a comparison of all strain gage readings at 100% limit load as taken from the strain data of Tables C-1 and C-2. This comparison shows that the strain measurements recorded during 9 August 1978 test loadings were essentially identical to those taken during the 8 August test loadings at all strain gage locations.

Figures C-23 and C-24 present overall views of the upper and lower cover skin and rear spar cap strains at 150%  $D_{\bullet}L_{\bullet}L_{\bullet}$

Figure C-23 Upper Cover and Rear Spar Cap Recorded Strains at 150% D.L.L. C-36

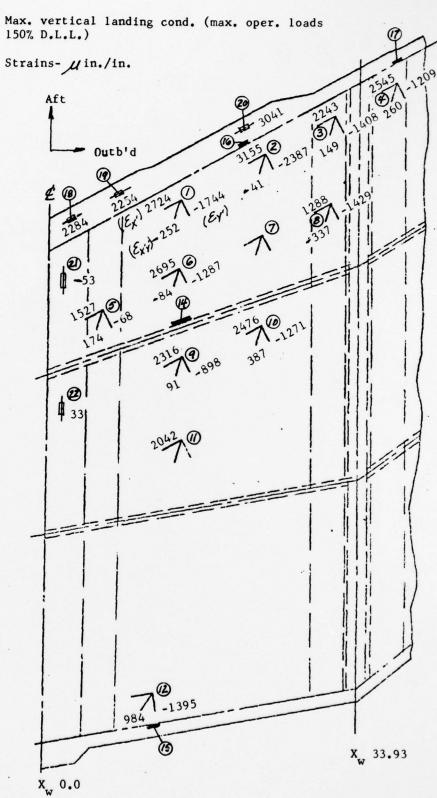

Figure C-24 Lower Cover and Rear Spar Cap Recorded Strains C-37

Comparisons of predicted and measured strains at the 150% D.L.L. level are presented in Table C-4. Predicted strain values are calculated from a NASTRAN stress analysis of the composite wing box test section which simulates the test setup restraint conditions as noted in Paragraph C-2. The basic NASTRAN model utilizes triangular CTRIA 1 sandwich plate elements which have their "X" axis oriented normal to the airplane center line in the inboard portions of the wing box as shown in Figures C-7 and C-8.

The wing cover rosette gages are located with the "A" legs parallel to the rear spar which is swept aft at a 28.35° angle with respect to an axis normal to the airplane center line as shown in Figure C-18. A 28.35° rotation of the NASTRAN stresses is required to calculate strains in the laminate parallel and perpendicular to the rear spar axis as shown in Figure C-25.

The following sample calculations are shown to illustrate the rotation of NASTRAN stresses from the X-Y reference system to the X'-Y' reference system at upper cover rosette gage location 1:

$$f_{x} = -31,312 \#/in^{2}$$

$$f_{y} = -1140 \#/in^{2}$$
Ref. NASTRAN Stresses
$$f_{xy} = -7747 \#/in^{2}$$

$$\theta = 28.35^{\circ} (\text{Ref. Figure C-25})$$

$$f_{xy} = \frac{f_{x} + f_{y}}{2} + \left[\frac{f_{x} - f_{y}}{2}\right] \cos 2\theta + f_{xy} \sin 2\theta$$

$$= \frac{-31,312 - 1140}{2} + \left[\frac{-31,312 + 1140}{2}\right] \cos 56.7^{\circ} - 7747 \sin 56.7^{\circ}$$

$$= \frac{-30,984 \#/in.^{2}}{2}$$

$$f_{y'} = \frac{f_{x} + f_{y}}{2} - \left[\frac{f_{x} - f_{y}}{2}\right] \cos 2\theta - f_{xy} \sin 2\theta$$

$$= \frac{-31,312 - 1140}{2} - \left[\frac{-31,312 + 1140}{2}\right] \cos 56.7^{\circ} + 7747 \sin 56.7^{\circ}$$

$$= \frac{-1468 \#/in.^{2}}{2}$$

$$f_{x'y'} = - \left[\frac{f_{x} - f_{y}}{2}\right] \sin 2\theta + f_{xy} \cos 2\theta$$

$$= \left[\frac{-31,312 + 1140}{2}\right] \sin 56.7^{\circ} - 7747 \cos 56.7^{\circ}$$

$$= 8356 \#/in.^{2}$$

\* Ref. MIL-HDBK-17A Pg. 3-17 (Mohr's Circle Rotation)

The corresponding strains in the X'-Y' reference system are determined in the following manner:

Material Properties:

$$\xi_{y'} = 2340 \mu \text{ in./in.}$$

F Ref. Advanced Composite Design Guide, Vol. IV, Page 4.2.7

$$f_{x'y'} = G_{x'y'} \left[ 2 \mathcal{E}_{x'y'} - (\mathcal{E}_{x'} + \mathcal{E}_{y'}) \right]$$

$$8356 = 3.85 \times 10^{6} \left[ 2 \mathcal{E}_{x'y'} - (-3608 + 2340)10^{-6} \right]$$

$$\mathcal{E}_{x'y'} = 451 \, \mu \text{ in./in.}$$

+ Ref. Advanced Composite Design Guide, Vol. IV, Page 4.2.7

Strain gages at location (12) (Reference Figure C-18) have their "A" legs oriented parallel to the front spar which is swept forward 18.1° from an axis parallel to the rear spar. The laminate axial moduli, shear modulus and Poisson's Ratios for this strain angle were determined from transformation calculations described in AFML-TR-78-33 dated March 1978.

The comparison of measured and predicted strains presented in Table C-4 shows reasonable correlation in most areas of the test box structure. In general, the calculated strains are conservatively higher than the measured strains. In all cases the biaxial strain patterns of the orthotropic cover skin laminates are in the direction and proportion predicted by the NASTRAN analysis.

Factors which may contribute to differences in predicted and measured strains include the following:

- Bending stiffness of spar webs was not included in the NASTRAN model.
- Skin thickness in areas of tapering laminate thickness adjacent to the centerline rib and B.P. 33 rib may not be accurately represented.
- Difficulty in calculating the strain at the exact gage locations due to the fact that the NASTRAN model provides only an average strain in each cover skin element and the gradient between adjacent elements is rather steep in some cases.
- Possible variations in calculated and actual modulus values of the orthotropic cover skin laminates.
- Tolerance in the accuracy and repeatability of strain gage measurements.
- Small differences in test load application versus NASTRAN model load application.

In summary it may be stated that the NASTRAN analysis provided a conservative representation of the internal stress distribution and accurately identified the pattern of strain distribution throughout the structure.

#### C-5-3 Comparison of Predicted and Measured Deflections

Table C-5 presents a comparison of predicted and measured deflections. The measured deflections include a correction based upon an approximate upbending rotation of  $0.19^{\circ}$  at the root of the forward spar as measured by deflection transducers 32 and 33. Bending rotation at the root of the rear spar was too erratic to be utilized. Excellent agreement is shown between all the measured and predicted deflections with the measured values slightly less than the predicted values.

### C-6 FATIGUE LOAD TEST

#### C-6-1 Fatigue Load Spectrum

A landing load fatigue test spectrum was determined for the composite wing box test section based upon the V/STOL landing criteria specified for the XFV-12A prototype aircraft. This criteria is defined in "NR-356 V/STOL Technology Design Criteria Report" (NR72H-330-2) and conforms to the requirements of MIL-A-8866. Figure C-26 presents the V/STOL sink speed probability curve for the XFV-12A based upon a maximum vertical sink speed of 15 feet per second.

Table C-6 presents the fatigue test load distribution to be applied for each 1000 flight hours based on the probability distribution of Figure C-26.

TABLE C-6
V/STOL LANDING LOAD SPECTRUM
FOR EACH 1000 FLIGHT HOURS

Sink Speed V v (Ft./Sec.)	Probability	<u>∑</u> N 1000	N 1000	$v_{\mathbf{v}}^{2}$	$ \frac{v_{v}^{2} \times 100}{225} $
15	.001	1	1	225	100.00
14	.003	3	2	196	87.11

2	1.000	1000	30	4	1.78

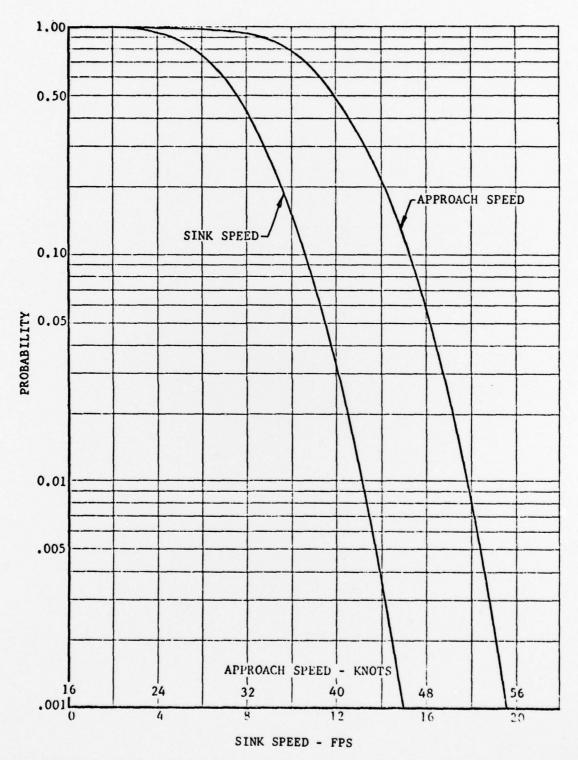

Figure C-26 Probability of Exceeding Sink Speed and Approach Speed for XFV-12A V/STOL Landings

### C-6-1 Fatigue Load Spectrum (Cont'd.)

This spectrum was applied twelve times to the composite wing box test section to represent two lifetimes of service based upon 6000 flight hours per lifetime. The loading spectrum was truncated at 21.78% of maximum load and the sequence of loading progressed from 21.78% to 100% of maximum load in each of the twelve blocks of loading.

#### C-6-2 Fatigue Load Test Results

Two lifetimes of the fatigue load spectrum of Paragraph C-6-1 were completed on 20 September 1978. There was no evidence of damage or permanent deformation in the composite wing box test section as a result of this series of test loadings. Strain gage measurements taken at the 100% fatigue test load level were essentially identical to those recorded during the static test loadings at the max. operational load level (150% D.L.L.).
